FIG. 7.

FIG. 6a FIG. 6b.

2167041

1

A DISPENSING VALVE

This invention relates to a valve more particularly, but not exclusively, to a valve usable with a chemical dispenser for discharging an amount of lavatory cleaner held in the dispenser to a lavatory cistern after each flush.

Lavatory chemical dispensers have been proposed, for example, as manufactured as under the trade name "Depend-O" in which a valve assembly attached to a bottle of toilet cleaning chemical, is used to dispense an amount of chemical into a lavatory after each flush. The valve mechanism is opened, under the action of gravity, when the cistern is flushed, and is closed by a bouyancy force, generated in an inverted cup-shaped member which retains air when the cistern is full of water, to push the valve member into the closed position.

The valve mechanism is arranged to restrict the amount of chemical dispensed by using an external sleeve-shaped holding, member attached to the valve. The holding member fills up with chemical which drips out of the bottle when the valve is opened. The chemical is

replaced by air entering the bottle from the cistern through the top of the holding member, until the chemical filling the holding member blocks the air passage into the bottle at which time the flow of chemical into the holding member stops. The chemical is dispensed from the holding member by displacement when the valve is closed.

It is a disadvantage of such a proposed dispenser that the amount of chemical dispensed is not precise.

It is a further disadvantage that the dispenser is unsuitable for use in both big and small tanks.

According to the invention, there is provided a dispensing valve for sealing an opening in a container which opening defines a valve seat and for dispensing liquid from a said container, the valve comprising a chamber movable between a filling position in which the chamber is fillable with liquid from the container and a discharge position in which liquid held in the chamber may be discharged, the chamber being movable through the opening between said positions and having at least one filling and discharge opening and a groove extending from the filling and discharge opening, the groove reducing in cross sectional area away from the filling and discharge opening in a direction from the filling

It is a preferred feature of the invention that first and second sealing means are provided for sealing the chamber in said fill up and discharge positions respectively relative to a seat which is attachable to the dispenser.

It is a further preferred feature of the invention that the liquid transfer volume of the chamber is adjustable.

An embodiment of the invention will now be described by way of example with reference to the accompanying drawings in which:

Figure 1 is a prespective view of a chemical dispenser incorporating the invention.

Figure 2 is an exploded cross-sectional view of the discharge assembly.

Figure 3 is a non-sectional view taken in the direction of arrow A of figure 2.

Figures 4 and 5 show the embodiment of figures 1 to 3 in use.

Figures 6a and 6b show detail of the mounting pieces, for mounting the dispenser shown in figure 1 on the cistern side.

Figure 7 shows detail of a packaging arrangement for the embodiment of figures 1 to 6.

With reference to figure 1, a chemical dispenser generally designated 1 is shown. The dispenser 1 is attached to the side of a lavatory cistern 3, in a manner to be described later. The dispenser 1 includes a liquid chemical container 5 which is filled with liquid cleaning and deodorising chemical 7. The dispenser 1 is provided at its base, with a discharge assembly 9, through which the chemical 7 is discharged into the cistern 3 every time the cistern 3 is flushed. The container 5 is further provided with a stopper 11 which allows the dispenser 1 to be refilled with chemical 7 as necessary. The stopper 11 affects an airtight seal and is preferably screw threaded, the seal being provided by a piece of silicone material 12 inside the cap 11. (For detail, see figure 7).

The discharge assembly 9 will be described in greater detail with reference to figures 2 to 5. In figure 2, the assembly 9 is shown in cross section. As illustrated, the assembly 9 includes a valve member 13 and a valve seat 15.

The valve member 13 includes a transporting chamber 17 of hollow, cylindrical form, having two elongate openings 25 formed in the sides thereof which includes a cap 19. The cap 19 is provided with an annular groove 21 into which a silicone material washer 23 is fitted. Grooves 26 are provided, extending from each opening 25, each groove 26 reducing in cross section away from the opening 25.

The chamber 17 is further provided with a adjustable silicone rubber plunger assembly 27 which includes a plunger 29, attached to a threaded member 31. The threads of the threaded member 31 engage with corresponding threads in a end piece 33, which is attached to the chamber 17 by means of complimentary threaded portions 35, 36. The inner threads 31, 32 and outer threads 35, 36 are arranged to be contra rotating, as described below.

The end piece 33 is further provided with an annular groove 37 in which a further silicone washer 39 is fitted. The washer 39 has a beveled surface as shown.

A float 41 is preferably formed in one piece with the threaded member 31. The float 41 is provided with an annular depression 42 in its upper surface.

Turning to the valve seat 15, this is provided with a cylindrical opening 43 of sufficient diameter to accomodate the chamber 17 with a slight clearance. As will be described below, in use the valve member 13 moves between its discharge position, in which silicone washer 23 abuts against surface 45 of the valve member 15, and a fill-up position in which silicone washer 39 abuts against slightly beveled surface 47 of the valve seat 15. The valve seat 15 is formed as part of a stopper 49 which engages, in a press fit with the chemical container 5.

The working of the chemical dispenser 1, and in particular the discharge assembly 9, will now be described with reference to figures 4 and 5.

With reference to figure 4, the dispenser 1 is shown positioned in the cistern 3, prior to flushing. The float 41 holds the discharge assembly 9 in the fill-up

position as shown. The silicone washer 39 abuts against surface 47, to form a seal preventing seepage of chemical 7 out through the discharge assembly 9. The chemical 7, however, fills the chamber 17, through the openings 25.

When the cistern 3 is flushed the water level decreases as shown in figure 5. The float 41 then ceases to exert a force holding the discharge assembly 9 in the fill-up position and the assembly 9 descends to the position shown in figure 5, in which the silicone washer 23 abuts against surface 45 thus preventing chemical 7 from escaping from the container 5 into the cistern 3. However, the amount of chemical 7 held in the transporting chamber 17 is transferred out of the container 5 and into the annular depression 42 through openings 25, as shown. Any small amount of chemical which overflows out of the depression 42 is discharged into the water at the end of the flush and forms a concentrated solution of chemical to aid cleaning of the lavatory bowl.

The volume of the chamber 17 can be adjusted by rotation of the float and threaded member 31 relative to the end piece 33, so that the plunger 29 moves in or out accordingly. As previously mentioned, the threaded

members 31, 32 have contra rotating threads to the threaded members 35, 36, this allows the plunger 29 to be moved outwardly without unscrewing the end piece 33. The plunger 33 is preferably pre-adjusted during manufacture to the minimum release position so that there should only be a requirement to increase the release of chemical. Adjustment of the amount of chemical allows the dispenser 1 and discharge assembly 9 to be uniformly effective in a wide variety of sizes of tank. Preferably, the transporting chamber is formed from translucent plastics material, for example polyethylene or nylon, so that the level of the plunger 29 is viewable through the chamber 17, the chamber 17 being marked with graduations indicating the preferred position of the plunger 29, for given sizes of cistern tank.

When the cistern refills, the water is coloured by the chemical previously released into the depression 42 and the float 51 moves up under action of the water pressure to displace the discharge assembly 9 into the fill-up position as shown in figure 4.

With reference to figure 6, holding pieces 49, 51 are shown. The holding pieces 49, 51 support the dispenser 1 relative to the side of the cistern 3, as shown in figure 1. The container 5 is provided with slots 53, 55, 57 and 59 formed on the sides of the container. Slots 53, 55 are arranged to receive the U-shaped holding piece 49, the base 50 of the U, abutting against the lower sides of two of the slots 55, the projecting ends of the U being bent so that the holding piece 49 hooks around the cistern 3. Similarly, the inverted T holding piece 51 engages in either of the slots 57, 59 and is bent to hook onto another side of the cistern 3.

The holding piece 51 provides greater support, but it is not essential, for holding the dispenser 51 in place. A plurality of openings 55 are provided so that the holding piece may have an adjustable position in case of obstruction at the side of the cistern 3.

The container 5 is provided with a flat side surface, in which openings 55 are disposed and an arcuate side surface in which openings 53 are disposed. The different side surfaces allow the dispenser 1 to fit against both flat-sided and arcuate sided cistern tanks. The arcuate side preferably forms an arc of a 30 centimetre diameter circle.

With reference to figure 7 the dispenser 1 is shown, having a cap 61 attached thereto. The cap 61 is frictionally fitted onto the container 5 and is of sufficient size to exert a slight force against the float 41 of the discharge assembly 9. This in turn acts on the silicone washer 39, which seals the container against surface 47 so that during transit and when on display, in a shop for example, the dispenser 1 is sealed to prevent seepage of chemical.

The container 5 is preferably manufactured from polyethylene. The remaining working parts with the exception of the silicone washers and plunger are also preferably manufactured from plastics or other corrosion resistant, materials, for example polyethylene or nylon.

The float 41 may be replaced by a inverted cup-shaped member which traps air beneath it, when the cistern refills, so as to act as a float.

A preferred feature of the invention is that the distance between the first and second sealing surfaces is constant, independent of the volume of the chamber.

Claims

1. A dispensing valve for sealing an opening in a container which opening defines a valve seat and for dispensing liquid from a said container, the valve comprising a chamber movable between a filling position in which the chamber is fillable with liquid from the container and a discharge position in which liquid held in the chamber may be discharged, the chamber being movable through the opening between said positions and having at least one filling and discharge opening and a groove extending from the filling and discharge opening, the groove reducing in cross sectional area away from the filling and discharge opening in a direction from the filling position to the discharge position.

2. A valve as claimed in claim 1 wherein the chamber has an adjustable volume.

3. A valve as claimed in claim 1 wherein the chamber is interposed between first and second sealing surfaces for sealing said opening which defines the valve seat in said filling and discharge positions respectively.

4. A valve as claimed in claim 3 wherein the first

5. A valve as claimed in claim 3 or claim 4 wherein the second sealing surface comprises a sealing member formed from elastomeric material.

6. A valve as claimed in claim 2 or any claim dependent thereon further comprising a plunger movable in the chamber so as to adjust the volume thereof.

7. A valve as claimed in claim 6 wherein the plunger and chamber are connected through complementary threaded portions so that relative rotation of the chamber and the plunger causes adjustment of said volume.

8. A valve as claimed in any one of the preceding claims, further comprising float means, connected to the chamber.

9. A valve as claimed in claim 8 wherein the float means is provided with a depression, arranged so that, in use, liquid discharge from the chamber is received in the depression.

10. A valve as claimed in claim 3 as dependent on claim 2 wherein the distance between the first and second sealing surfaces is constant, independent of the volume of the chamber.

11. A dispenser comprising a container for liquid and a valve as claimed in any one of the preceding claims.

12. A dispenser as claimed in claim 11 wherein the container is provided with means for attachment of the dispenser to the side of a lavatory cistern, one of the sides of the container being arcuate and another of the sides of the container being flat.

13. A dispenser as claimed in claim 11 or claim 12 further comprising a cap arranged to force the valve into a sealing position against the container opening.

14. A valve substantially as hereinbefore described with reference to the accompanying drawings.

15. A dispenser substantially as hereinbefore described with reference to the accompanying drawings.
